

Abstract

William J. Pate

Inhalation Exposure from Showering with Contaminated Water

Benzene concentrations in air resulting from showering with contaminated water are estimated by air sampling and modeling. The modeling involves calculating benzene concentrations in air after measuring inlet and outlet benzene concentrations in water, water flowrate, and bathroom dimensions. Based on benzene in air concentrations, inhalation exposure is calculated and compared to exposure resulting from ingestion of the same contaminated water. The results of this project indicate that showering with contaminated water may be a major source of indoor air contaminants and that inhalation exposure may be equal to or greater than ingestion exposure.

Acknowledgments

Several people contributed to the completion of this project. Dr. John Freeman and Nancy Garrett, North Carolina Environmental Epidemiology Section, provided administrative support. Linda Perry and Kay Mitchell provided clerical support. John Neal and the staff of the State Laboratory of Public Health, Environmental Sciences Section, provided sampling supplies and analytical support. Debby Taylor, North Carolina Groundwater Section and Tad Helmstetler, Rowan County Health Department assisted in gaining access to sampling sites. Andrew Lindstrom, NSI Technology Services Corporation and Ross Highsmith, U.S. Environmental Protection Agency provided consultation and reference information. Committee members, Dr. Alvis G. Turner, Dr. Mildred A. Berry, and Dr. Michael Flynn provided suggestions and guidance. I thank all of these people for their help with this project.

I. INTRODUCTION

Many groundwater and surface water sources are contaminated with volatile organic compounds (VOCs). This contamination may be caused by leaking underground storage tanks or spills from industrial or waste treatment facilities. Environmental and health agencies have adopted standards or guidelines for acceptable water concentrations of many VOCs. These acceptable concentrations are derived from risk assessment of ingestion exposure to water-containing VOCs. In determining acceptable concentrations, agencies have not considered inhalation or dermal absorption exposures that may occur from domestic water use. When VOC concentrations exceed the standard or guideline, agencies recommend that people not drink the water. Often people comply with this recommendation by drinking bottled water. Citizens may continue to use the contaminated water for washing clothes and dishes and for bathing. By doing this, people avoid ingestion exposure, but may be subject to inhalation and dermal exposure.

This paper evaluates indoor air contamination and inhalation exposure resulting from the use of contaminated water for showering. These concentrations and exposures are estimated by air sampling and by modeling.

II. LITERATURE REVIEW

Several scientists have evaluated the release of contaminants from water into air. Pritchard and Gesell²⁴ measured the inlet and outlet radon content of water for several specific water uses. They determined that the radon transfer efficiency from water to air was 30 to 90 percent depending on the specific water use. The transfer efficiency for showers was 63 % and for washing machines and dishwashers was 90%. Considering the volume of use and the transfer efficiency for specific water uses, Pritchard and Gesell estimate that the volume-use weighted mean transfer efficiency is approximately 50%. Hess¹⁵ determined that radon transfer efficiencies for showers was 65% and for dishwashers was 98%.

Andelman⁴ evaluated the volatilization rate of chloroform and trichloroethylene in a laboratory shower. The chemical concentration in the inlet was controlled and the water draining from the shower was sampled every 10 minutes during a 60-minute shower. Andelman varied the following parameters to evaluate their effect on volatilization: (1) contaminant concentration in water; (2) water temperature; (3) height of air sampling port; and (4) diameter of shower head holes. The study determined that increases in the magnitude of the following variables increased the extent of volatilization: water temperature; chemical concentration in water and height of shower head. The extent of volatilization increased with decreasing size of shower head holes. This study detected a volatilization rate of approximately 50% for chloroform and 80% for trichloroethylene during a 60-minute shower. Andelman found that as air concentration increases over the duration of the sixty-minute shower, the percent

volatilization decreases. The reason for this is that as the air concentration increases, the gradient between the water concentration and air concentration decreases. For example, Andelman detected 82% volatilization after 10 minutes of shower operation, 70% after 30 minutes, and 62% after 50 minutes.

Henry's law is the relationship between a chemical concentration in air and the concentration of that chemical in water, at equilibrium. Henry's law is represented by the equation: $H = Ca/Cw$, where H is Henry's law constant and Ca and Cw are concentrations of the chemical in the air and water phases, respectively. The H values can be estimated by the ratio of vapor pressure to water solubility for a specific compound. A compound with a low vapor pressure and a low water solubility may have a Henry's law constant that is similar to a Henry's law constant for a compound that has a high vapor pressure and a high water solubility.

Andelman determined that shower air concentrations are below what is predicted by Henry's law. Andelman reported that Henry's law would predict an upper limit for air concentrations.

A study by Rathbun and Tai²⁵ determined that the mass-transfer coefficient for the transfer of a chemical from water to air changes very little over several orders of magnitude of concentration. This indicates that the percent volatilization is not affected significantly by the water contaminant concentration.

McKone,¹⁶ Andelman,¹⁻⁵ and others have used modeling and measurement to estimate air contaminant concentrations resulting from the use of contaminated water. Pritchard and Gesell used a model to estimate

air concentration of radon in the bathroom when the shower operates for five (5) minutes, the bathroom volume is 30,000 liters, the water used is 75 liters, and the transfer efficiency is 63%. It should be noted that this model does not consider air exchange rate during the showering time period. Ignoring the air exchange rate should have little effect on the estimated air concentration because of the short-time duration of the shower. The model predicts the following relationship:

$$Ca = (1.6 \times 10^{-3}) Cw$$

where Ca is the air concentration and Cw is water concentration of radon in picoCurries per liter.

McKone developed a three compartment model to estimate concentrations in the shower, bathroom, and remaining house. He used transfer efficiencies of 70% for the shower, 30% for the toilet, and 66% for other household water uses. The model incorporates the following water volume uses: showers and baths, 300 liters; toilets, 300 liters; and other household uses, 400 liters. The duration of the shower is 10 minutes per individual. The volume of the bathroom is 10,000 liters, and the volume of the remaining house is 400,000 liters. The model uses a residence time of household air of 120 minutes (0.50 air changes per hour). This model was used to consider exposure to chloroform, ethylene dibromide, dibromochloropropane, methylchloroform, perchloroethylene, trichloroethylene, and carbon tetrachloride. McKone's model derived the following relationship between contaminant concentration in water and in air:

(1) for the shower compartment

$$Ca = (1.7 \text{ to } 9.3) \times 10^{-2} Cw.$$

(2) for the bathroom compartment

$$Ca = (1.8 \text{ to } 3.8) \times 10^{-3} Cw.$$

(3) for the house compartment

$$Ca = (0.10 \text{ to } 0.72) \times 10^{-4} Cw.$$

Ca is the air contaminant concentration and Cw is the water contaminant concentration in milligrams per liter.

Andelman⁴ used a one-compartment model to estimate indoor air concentrations resulting from the use of contaminated water. The model uses 50% volatilization to represent all indoor water uses and assumes "typical air exchange and other pertinent home parameters." (Andelman cites reference 27 for these assumptions.) This model derived the following relationship:

$$Ca = (0.1 \text{ to } 5) \times 10^{-4} Cw.$$

In a laboratory setting, Andelman measured 50-80 mg/m³ of trichloroethylene (TCE) in the shower air during a 60-minute shower which used water containing 3.8 mg/l TCE. McKone's model predicted that the air concentration would be 68-100 mg/m³.

Wallace et al,³⁰ as part of the TEAM studies, conducted air sampling in homes for volatile organic compounds. This sampling detected chloroform and bromodichloromethane in air in homes that had these two contaminants in water. The measured air concentrations for these compounds are consistent with McKone's model estimates for house air concentrations.

McKone used the model to calculate lifetime inhalation exposure to volatile compounds coming from the use of contaminated water. These calculations considered the exposure occurring in each of the three compartments (shower, bathroom, and house) for infants, children, and adults. Two ranges of exposure parameters were used to calculate reference and upper-bound exposure estimates. The reference estimates for adults included the following: (1) 10 minutes per shower per day; (2) 40 minutes spent in the bathroom per day; (3) 15 hours spent in the house per day; and (4) 50% uptake of chemical. The upper-bound estimates for adults included the following: (1) 20 min/shower per day; (2) 60 minutes spent in the bathroom per day; (3) 24 hours spent in the house per day; and (4) 100% uptake of chemical. McKone evaluated exposure to chloroform, ethylene dibromide, carbon tetrachloride, dibromochloropropane, 1,1,1-trichloroethane, tetrachloroethylene, and trichloroethylene. This model estimated that the inhalation exposure attributable to contaminated water can be between 0.8 and 6.0 times the exposure attributable to the consumption of 2 liters per day of contaminated water by a 70 Kg adult. McKone projects that more than half of the lifetime inhalation exposure will occur in the shower and one-third will occur in the bathroom.

Andelman⁷ calculated inhalation exposure for the time spent in the shower and bathroom. This calculation incorporated the following assumptions: (1) 75% volatilization of the chemical from water to air; (2) shower duration of six (6) minutes; (3) time in bathroom after the shower is 12 minutes; (4) the breathing rate is 1000 liters per hour; (5) the shower water flow is 500 liters per hour; (6) the air exchange rate is 0.53

per hour; (7) the bathroom volume is 10,000 liters; and (8) there is 100% uptake of the chemical. This calculation predicted that the inhalation exposure would be equal approximately to drinking one liter of the contaminated water per day.

In addition, Andelman calculated the inhalation exposure that would occur in the entire house from use of contaminated water over a 24-hour time period. This calculation assumed 50% chemical volatilization for all water uses and estimated that inhalation exposure will be 0.1 to 5.0 times ingestion exposure when ingestion is 2 liters of water per day.

Foster and Chrostowski¹⁴ developed and used a model to estimate inhalation exposure to volatile organic compounds while showering and being in the bathroom after the shower is completed. This model was used to calculate concentrations in upper- and lower-bound scenarios. The model assumes the following:

Shower duration:	10 min. (lower-bound scenario)
	15 min. (upper-bound scenario)
Water flow rate:	10 l/min
Water temp.:	45° C
Shower room volume:	6 m ³
Air exchange rate:	1.5 hr. ⁻¹ (lower-bound scenario)
	0.5 hr. ⁻¹ (upper-bound scenario)
Water concentration:	15 ug/l (lower-bound scenario)
	75 ug/l (upper-bound scenario)
Adult weight:	= 70 Kg

The model estimates that inhalation exposure to benzene will be 0.224 to 2.26×10^{-3} mg/kg/day. Comparing this inhalation exposure to ingestion exposure resulting from drinking two (2) liters of water per day, one finds that inhalation exposure is 0.52 to 1.06 times the ingestion exposure for the lower- and upper-bound scenarios.

James and Knuiman,¹⁶ from a survey of 2500 Australian homes, report that the mean shower flow rate is eight (8) liters per minute and the mean shower duration is six (6) minutes. Based on a study of modern houses in one heating season, Nazaroff et al.,²⁰ reported that the mean air exchange rate is 0.53 air changes per hour. Bond et al.,⁹ report the following water consumption rates:

<u>Water Use</u>	<u>Volume (liters per person per day)</u>
toilets	35-95
showers & baths	25-75
laundry	28-44
dishwasher	14
kitchen and sinks	19-68
cleaning	13-30
TOTAL	134-326

The information reported in the literature is summarized in Tables 1, 2, and 3. Table 1 lists the volatilization rates for various contaminants for different water uses. The range of volatilization rates is from 30 to 98 percent. Table 2 lists the ratios of air concentration to water concentration in the shower, bathroom, and house. The range of ratios for the shower is 1.6 to 93×10^{-3} , for the bathroom is 1.8 to 3.8×10^{-3} ,

and for the house is 0.1 to 5×10^{-4} . Table 3 lists the ratios of inhalation exposure to ingestion exposure for inhalation exposures that occur in the shower and house. The range of ratios for the shower is 0.47 to 1.06 , and for the house is 0.1 to 6 .

III. SAMPLING PROTOCOL

Air and water sampling were conducted during shower operation in four homes that were known to have contaminated groundwater. Sampling was repeated in two of the homes so that there were six repetitions of the sampling protocol. There was a time lapse of 20 days between samples at one home and a time lapse of 47 days at another home.

Homes were selected whose water was known to be contaminated with benzene in the range of 400 to 2600 micrograms per liter (ug/l). The benzene concentrations in water at the homes changed with time, so that at the time of this study one home had nondetectable concentrations of benzene, one had approximately 3000 ug/l, and two had approximately 1000 ug/l.

Air sampling and analysis was conducted according to NIOSH method 1501, "Sampling and Analysis for Aromatic Hydrocarbons."²² This method is intended for use in occupational exposure settings and recommends sampling at 0.20 liters per minute through a charcoal tube that contains 100 milligrams of charcoal in the front section of the tube and 50 milligrams in the back-up section of the tube. The method was modified by sampling at a flow rate of 1.0 liter per minute through a charcoal tube containing 400 milligrams of charcoal in the front section of the tube and 200 milligrams in the back-up section of the tube. In addition, the method was modified to include a water filter tube¹⁷ containing 5A molecular sieve upstream of the charcoal tube. It was necessary to use the water filter tubes to protect the charcoal from the high humidity in the shower air.

The air sampling duration had to be sufficient to collect an amount of benzene that is detectable by the analytical method. Based on the following information, it was determined that the shower operation and air sampling duration be 30 minutes:

- the analytical detection limit for benzene using this sampling and analytical method is 0.02 milligrams per sample.
- the ratio of contaminant concentration in air to contaminant concentration in water is reported in the literature to be in the range of 1.6 to 9.3×10^{-3} for showers. Andelman reported that this ratio is 0.1 to 5×10^{-4} in the whole house.
- the air sampling flow rate was 1.0 liter per minute.

Air sampling was conducted in triplicate in the breathing zone for the duration of a thirty-minute shower and in the bathroom for the twenty-minute period following the shower. A fifty-minute air sample was collected in the bathroom during the shower including 20 minutes after the shower. Five air samples were collected in the bathroom for each sampling protocol.

During each thirty-minute shower period, three water samples were collected from the shower head (designated inlet samples) and from the bottom of the shower (designated outlet samples). The outlet samples were collected by placing a small pan on the floor of the shower to collect shower water. The water in the pan was transferred to a glass sample container. Inlet and outlet samples were taken at approximately 5, 15, and 25 minutes after the start of the thirty-minute shower.

The water flow rate for the shower was measured three times during each shower period by measuring the time it took to fill a volumetric container. The shower water temperature was also measured three times during the shower period. The temperature and flow rate measurements were made near the start, middle, and end of the shower. Bathroom dimensions were measured and the volume of the air space in the bathroom was calculated.

The relative humidity in the bathroom was measured during two shower periods and was found to be 100%. No further measurements of relative humidity were made.

IV. SAMPLING AND CALCULATION RESULTS

Estimation of the benzene concentrations were made by measurement and by calculation. In order to calculate benzene concentrations, it was necessary to measure the following parameters:

- benzene concentration in water, C_w
- water flow rate, F_w
- bathroom air volume, V
- percent volatilization, f

For these calculations, it was assumed that the air exchange rate was 0.53 air changes per hour, that there was complete mixing in the bathroom/shower, and that none of the benzene that volatilized from the water adhered to the walls or other surfaces in the bathroom. The following equations were used for the calculations (REFERENCE 23):

$$G = C_w \times f \times F_w \times 60$$

$$C = \frac{G}{Q} + \frac{V}{QT} \left[\frac{-G + G \exp \frac{-Qt}{V}}{Q} \right]$$

G = rate of generation of contaminant (mg/hr)

C_w = contaminant concentration in water (mg/l)

f = volatilization fraction

F_w = water flow rate (l/min)

Q = rate of ventilation (room volume X air changes per hour) (l/hr)

t = duration of shower (hr)

V = volume of bathroom

The air concentration of the contaminant was measured three times in the shower and twice in the bathroom. The five air measurements were averaged to estimate the air concentration in the bathroom. In some cases, five samples were not available because of a sample pump malfunction.

Results are shown in the following tables:

Table 4 Benzene Concentrations in Water

Table 5 Measured Water Parameters

Table 6 Measured Water and Air Concentrations of Benzene in Showers in Selected Homes

Table 7 Air Concentrations of Benzene in Showers in Selected Homes

In summary, the percent volatilization of benzene for concurrent pairs of inlet and outlet water samples ranged from 38.1% to 100%. The mean percent volatilizations for the triplicate inlet and outlet water samples for the five sample sites were 52.2%, 54.7%, 54.7%, 91.8%, and 99.8%. The ratio of measured concentration of benzene to calculated concentration for

the five sample sites ranged from 0.80 to 1.29. The ratios of the air concentration of benzene to water concentration was $4.59 \text{ to } 10.16 \times 10^{-3}$. The literature reports that the ratio of air concentration to water concentration in shower/bathroom after a 5 to 20 minute shower is 1.6 to 93.0×10^{-3} .

V. SENSITIVITY ANALYSIS

The data from the Coleman 2-8-90 sample was used to represent baseline conditions. Individual variables were changed to determine the effect on calculated air concentrations. These data are listed in Table 8. This analysis shows that changing the shower duration results in the greatest change in air concentrations. The volatilization rate and the contaminant concentration in the water have the next largest effect on the air concentration.

VI. INHALATION DOSE AND RISK ESTIMATES

Inhalation doses and cancer risks were calculated for reasonable and worse case exposures. These calculations are shown in Figure 1. The parameters for each of these exposures are presented in Table 9. The mean measurement values were used for the water flowrate and bathroom air volume parameters in the reasonable exposure estimate.

If it is assumed that the water contaminant concentration is 1.0 milligram per liter, the reasonable case estimate of inhalation dose is 0.64 milligrams per day and the worse case estimate is 10.9 milligrams per day. If an adult drinks two liters of this water per day, the ingestion dose would be 2.0 milligrams per day. Based on these parameters and calculations, the ratio of inhalation to ingestion dose is 0.3 for the reasonable case estimate and 5.5 for the worse case estimate. The ratios reported in the literature range from 0.47 to 1.06.

If the water contaminant concentration was 1.0 milligram per liter, the reasonable case estimate of increased cancer risk due to benzene exposure is 2.65 cancer cases per 10,000 people exposed for a 70-year lifetime (2.65×10^{-4}). The worse case estimate is 45.16×10^{-4} .

$$D_{xs} = 0.22 \text{ mg/day}$$

C₂ = air concentration in bathroom after shower

$$C_2 = \frac{V}{Qt} (C_1) \left[1 - \exp^{-\frac{Qt}{V}} \right]$$

$$C_2 = 0.0021 \text{ mg/l}$$

D_{xb} = inhalation dose in bathroom

$$D_{xb} = C_2 \times B \times tb \times A$$

$$D_{xb} = 0.42 \text{ mg/day}$$

D_{xx} = total inhalation dose in shower and bathroom, reasonable case estimate

$$\begin{aligned} &= D_{xs} + D_{xb} \\ &= 0.64 \text{ mg/day (when water contaminant concentration is 1 mg/l)} \end{aligned}$$

Worse Case Calculations

G = pollutant generation rate

$$\begin{aligned} G &= C_w \times f \times F_w \times 60 \\ &= 1.0 \times 0.99 \times 10 \times 60 \\ &= 594 \text{ mg/day} \end{aligned}$$

Figure 1 (Cont'd)

C_1 = air concentration in shower

$$C_1 = \frac{G}{Q} + \frac{V}{Qt_s} \left[\frac{-G + G \exp \frac{(-Qt_s)}{V}}{Q} \right]$$

$$C_1 = 0.0115 \text{ mg/l}$$

D_{xs} = inhalation dose in shower

$$D_{xs} = C_1 \times B \times t_s \times A$$

$$D_{xs} = 4.59 \text{ mg/day}$$

C_2 = air concentration in bathroom after shower

$$C_2 = \frac{V}{Qt} (C_1) \left[1 - \exp \frac{t - t_{shower}}{V} \right]$$

$$C_2 = 0.0106 \text{ mg/l}$$

D_{xb} = inhalation dose in bathroom

$$D_{xb} = C_2 \times B \times t_b \times A$$

$$D_{xb} = 6.33 \text{ mg/day}$$

D_{tw} = total inhalation dose in shower and bathroom, worse case scenario

$$= D_{xs} + D_{xb}$$

$$= 10.9 \text{ mg/day (when water contaminant concentration is 1 mg/l)}$$

Reasonable Case Calculation

$$\text{Cancer risk} = D_{tr} \times \frac{1}{\text{Body Weight}} \times \text{Unit cancer risk value}$$

$$= 0.64 \text{ mg/day} \times \frac{1}{70 \text{ kg}} \times 2.9 \times 10^{-2} \text{ mg/kg/day}^{-1}$$

$$= 2.65 \times 10^{-4}$$

Worse Case Calculation

$$\text{Cancer risk} = D_{tw} \times \frac{1}{\text{Body Weight}} \times \text{Unit cancer risk value}$$

$$= 10.9 \text{ mg/day} \times \frac{1}{70 \text{ kg}} \times 2.9 \times 10^{-2} \text{ mg/kg/day}^{-1}$$

$$= 45.16 \times 10^{-4}$$

VII. SUMMARY

This study detected benzene volatilization rates of 38 to 100% and benzene in air concentrations of 8000 to 31,000 micrograms per cubic meter when contaminated water was used for 30-minute showers. These data indicate that showering with contaminated water may be a major source of indoor air contaminants. Inhalation exposure to these concentrations while showering may result in inhalation dose that may be greater than the ingestion dose that would occur if a person consumed 2 liters per day of the same water. Table 10 lists the volatilization rates, ratio of air concentration to water concentration, and the ratio of inhalation to ingestion dose for this study and for data reported in the literature.

In order to obtain more information about inhalation exposures resulting from the use of contaminated water, the following studies would be helpful:

- Conduct air sampling in showers while the shower operates for 10 minutes. Based on the literature, shower duration is 6-10 minutes.
- Conduct air sampling for other constituents including chloroform and tetrachloroethylene.
- Conduct air sampling in the living area and bedroom for a 24-hour time period.
- Collect and analyze urine or breath samples to evaluate exposure.
- Collect air samples with evacuated canisters¹³ if this sampling and analytical method has sufficient detection limit.

Table 10
Data Summary

	<u>Current Study</u>	<u>Literature Values</u>
Volatilization rate	38.1 - 100.0%	50 - 80%
Air/Water Concentration	$4.59 - 10.16 \times 10^{-3}$ ^a	$1.6 - 93.0 \times 10^{-3}$ ^b
Inhalation/Ingestion Dose	0.3 - 5.5	0.47 - 1.06

^a - for thirty minute showers

^b - for five to 20 minute showers
